#### 1 Graphs

#### 1.1 Scatterplot

We start in thinking about graphing change over time with a scatterplot.<sup>1</sup>

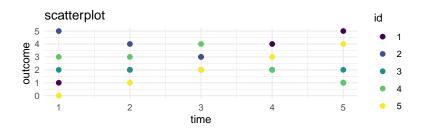

Figure 1: scatterplot

- <sup>1</sup> Scatterplots show every data point. However, with many data points, scatterplots may become overcomplicated, and difficult to interpret. Points may even be plotted over other data points.
- <sup>2</sup> Note that we are using *color* and *line type* to distinguish different individuals. This may not always be possible, especially when there are a large number of individuals in the data.

#### 1.2 Line Plot

A natural next step is to connect the dots of a scatterplot with straight line segments to form a line plot. <sup>3</sup>

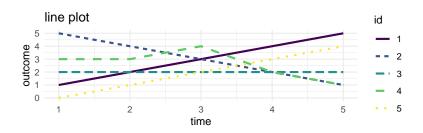

Figure 3: line plot

# <sup>3</sup> With any of the options discussed, one may consider *small multiples* where each individual trajectory is placed in its own sub-graph.

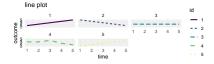

Figure 2: line plot with small multiples

#### 1.3 Spaghetti Plot

Instead of simply connecting the observations, one may estimate an individual linear trajectory. In *multilevel modeling* these line plots showing individual estimated linear trajectories are sometimes called *spaghetti plots*.

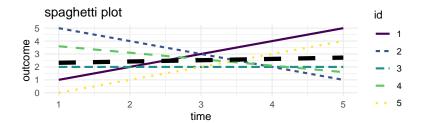

Figure 4: spaghetti plot

#### 1.4 Smoothed Trajectories

Alternatively, rather than connecting observations with straight lines, or estimating an overall straight line trajectory for each individual, it may be useful to *smooth* the trajectories by drawing curved lines between individual observations.<sup>4</sup>

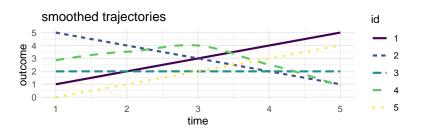

Figure 6: smoother plot

<sup>4</sup> One needs to be careful, however, as the smoothed trajectories may give the impression of having more data points than one actually has.

Figure 5: smoother plot with small multiples

#### 1.5 Slopegraph

An increasingly popular option is a slope graph.<sup>5</sup>

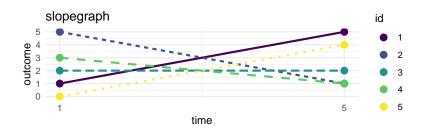

Figure 8: slopegraph

<sup>5</sup> In order to be clear and effective, a slope graph may often only show the outcome at the beginning point, and at the end point. A slope graph may be less satisfactory when there are multiple timepoints, unless the slopegraph shows *all* the timepoints. The small multiple idea works with a slopegraph as well.

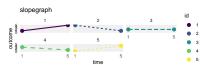

Figure 7: slopegraph with small multiples

# 2 These Graphs Require Data In Long Format

The data used in this example are *simulated*. Many data sets, but not all, are originally created in the *wide* format—as shown in Figure 10—where every row of data is an *individual*, and an individual only has a *single row*. Ideally, every row in *wide* data is uniquely identified by an individual *id* number.

id	outcome.1outcome.2outcome.3outcome.4outcome.5					
1	1	2	3	4	5	
2	5	4	3	2	1	
3	2	2	2	2	2	
4	3	3	4	2	1	
5	0	1	2	3	4	

Figure 10: wide data

Generally, for graphing change over time, it is most appropriate to have data that are in a *long* format, as shown in Figure 9. In *long* data every row represents a particular *measurement* occasion for a particular individual. Each individual in the data set thus has multiple rows. Ideally, every row in data in the *long* format is uniquely identified by the combination of an *id* number and a *study wave*.

Data can be *reshaped* from *wide* to *long* format, and *vice versa*. Two straightforward options are the reshape command as available in Stata and the pivot\_\*() commands available in R.
